# Part II: Generalized Linear Models

# Load Packages

Again, we must load the packages that will be used in the first part of this workshop.

```
library(pastecs, quietly = TRUE)
library(lm.beta, quietly = TRUE)
library(lmtest, quietly = TRUE)
library(foreign, quietly = TRUE)
library(lattice, quietly = TRUE)
library(lme4, quietly = TRUE)
library(nlme, quietly = TRUE)
library(survival, quietly = TRUE)
library(dplyr, quietly = TRUE)
library(ggfortify, quietly = TRUE)
library(survminer, quietly = TRUE)
library(rms, quietly = TRUE)
library(MASS, quietly = TRUE)
library(pscl, quietly = TRUE)
```

A generalized linear model (GLM) has three components:

- ▶ a random component with mean  $\mu$ . Generally, the random component is the response variable  $Y_i$ .
- ▶ a systematic component,  $\eta_i$ , that relates the explanatory variables,

$$\eta_i = \sum_{i=1}^n \beta_j x_{ij}$$

a link function that relates the mean of the random to the systematic component

$$g(\mu) = \eta_i$$

Logistic regression is a GLM used the model binary (0 or 1) data. The response variable must be binary and is assumed to follow a bernoulli distribution.

That said, logistic regression has the following components:

- ▶ a response binary variable,  $Y_i$ , that follows a bernoulli distribution with mean  $\pi_i$ .
- ▶ a systematic component,  $\eta_i$ , that relates the explanatory variables,

$$\eta_i = \sum_{i=1}^n \beta_j x_{ij}$$

a link function that relates the mean of the random to the systematic component

$$\log\left(\frac{\pi_i}{1-\pi_i}\right) = \sum_{i=1}^n \beta_j x_{ij}.$$

 $\log (\pi_i/(1-\pi_i))$  is known as the log odds.

#### Data

Using the iris data, we create binary data. We add the column Sepal.Width\_binary to iris. If the Sepal.Width is greater than the median then the associated value in Sepal.Width\_binary is 1. Otherwise, Sepal.Width binary is 0.

### Logistic Regression with only the constant term

Fitting only a constant term, the systematic component is

$$\eta_i = \beta_0$$
.

```
logit <- glm(Sepal.Width_binary - 1, data = data, family = "binomial")
summary(logit)</pre>
```

```
##
## Call:
## glm(formula = Sepal.Width binary ~ 1, family = "binomial", data = data)
##

## ATC: 201.22
```

# Logistic Regression with only the constant term

```
p_avg <- mean(data$Sepal.Width_binary)
log_odds_avg <- log(p_avg/(1-p_avg))
print(log_odds_avg)</pre>
```

```
## [1] 0.4895482
```

### Logistic Regression with Species

Fitting the species term, the systematic component is

$$\eta_i = 1 + \beta_2 X_{1i} + \beta_3 X_{2i}.$$

where

$$X_{1i} = \begin{cases} 1 & \text{if } i \text{th data point is versicolor} \\ 0 & \text{otherwise} \end{cases}$$

$$X_{2i} = \begin{cases} 1 & \text{if } i \text{th data point is virginica} \\ 0 & \text{otherwise} \end{cases}.$$

### Logistic Regression with Species

```
logit <- glm(Sepal.Width_binary ~ as.factor(Species), data = data, family = "binomial")
summary(logit)</pre>
```

```
##
## Call:
## glm(formula = Sepal.Width binary ~ as.factor(Species), family = "binomial",
      data = data)
##
##
## Deviance Residuals:
##
      Min
                10 Median
                                 30
                                         Max
## -2.5373 -0.8782 0.2857 1.0438 1.5096
##
## Coefficients:
                              Estimate Std. Error z value Pr(>|z|)
##
## (Intercept)

## ATC: 153.51
##
## Number of Fisher Scoring iterations: 5
```

### Logistic Regression with Species

Let's compare the results to the average log odds of each Species group

```
log_odds_avg_fun <- function(data){
    p_avg <- mean(data)
    log_odds_avg <- log(p_avg/(1-p_avg))
    return(log_odds_avg)
}

tapply(data$Sepal.Width_binary,
    data$Species, log_odds_avg_fun)</pre>
```

```
## setosa versicolor virginica
## 3.1780538 -0.7537718 0.3227734
```

The intercept corresponds to the average log odds of setosa as we would expect. However, the other coefficients do not correspond to the average log odds of the other species. Why?

### Logistic Regression with Species

From the formula,  $\eta_i = 1 + \beta_2 X_{2i} + \beta_3 X_{3i}$ , the log odds of versicolor actually corresponds to  $1 + \beta_2$ . The log odds of versicolor actually corresponds to  $1 + \beta_3$ .

## [1] 3.1780537 -0.7537718 0.3227734

Logistic Regression with continuous variable COMPLETE

## Logistic Regression with continuous variable, Sepal.Length

Fitting the species term, the systematic component is

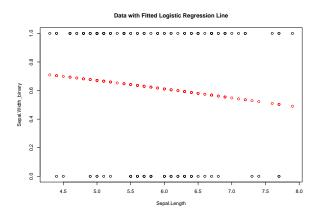

$$\eta_i = \beta_3 X_{1i}.$$

where  $X_{1i} = \text{Sepal.Length of the } i\text{th data point.}$ 

# Logistic Regression with continuous variable, Sepal.Length

```
##

### Logistic Regression with continuous variable, Sepal.Length

Plot the results for each species, we get that Scatter plot of sepal length vs sepal width

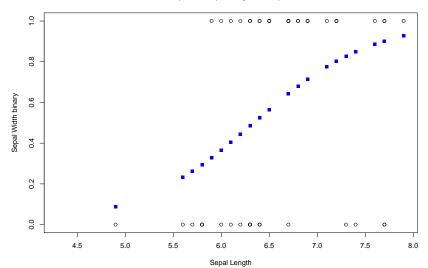

## Logistic Regression with continuous variable, Sepal.Length

#### Scatter plot of sepal length vs sepal width

### Logistic Regression with continuous variable, Sepal.Length

#### Goodness of Fit

#### Deviance

For general linear models, we use *deviance* to compare model pairs. Deviance is the difference in log likelihood of the models multipled by 2.

For a linear model, *deviance* is equivalent the sum of squares error of the residual.

#### Goodness of Fit

#### Saturated Model

Let's consider model in which each data point has its own mean and coefficients. This is called the saturated model. It basically replicates the data at hand.

Using deviance, we can compare our fitted model to a saturated model.

If the fitted model is behaves similiar to the saturated model, then the deviance can be well approximated by a chi-squared distribution with m-n degrees of freedom. m is the number of the data points and n is the number of coefficients in our fitted model.

#### Goodness of Fit

#### Saturated Model

This statistical property of the deviance allows us perform a hypothesis test

 $H_0$ : the fitted model is equivalent to the saturated model

 $H_{\alpha}$ : the fitted model is not equivalent to the saturated model

#### Goodness of Fit

#### Saturated Model

logit\$deviance is the deviance between saturated model and fitted model.

logit\$df.residual is equal to number of observations minus the number of coefficients in the fitted model.

Using this, we can calculate the p value for the hypothesis test above.

```
## [1] 0.8032738
```

Since the p value is greater than 0.05, we fail to reject the null hypothesis. (This is a good thing.)

#### Goodness of Fit

#### Null Model

We can also use deviance to determine if our fitted model is better than the null model. The null model is a model with only a linear term.

Like above, we can design a hypothesis test comparing the null model to the fitted model.

#### Goodness of Fit

#### Null Model

 $H_0=$  the fitted model is equivalent to the null model  $H_lpha=$  the fitted model is not equivalent to the null model

In the limit of large data, it is known that the deviance follows a chi-squared distribution with parameter n-1.

#### Goodness of Fit

#### **Null Model**

logit\$deviance is the deviance between saturated model and fitted model. logit\$df.residual is equal to number of observations minus the number of coefficients in the fitted model.

logit\$null.deviance is the deviance between saturated model and the null model. logit\$df.null is the number of observations minus 1.

#### Goodness of Fit

#### Null Model

Using this information, we can calculate the p value for the hypothesis test above.

```
## [1] 1.173879e-14
```

Since the p value is less than one, we reject our null hypothesis. (This is a good thing.)

#### Goodness of Fit

#### Anova

anova with argument test="Chisq" allows us to compare change in deviance after sequencially adding terms our model.

```
anova(logit,test="Chisq")
```

```
## Analysis of Deviance Table

```

A possion GLM is used to study *count* data (i.e. discrete numbers,  $0, 1, 2, \cdots$ ). *Count* data describes the number of events that occur within a given time frame.

insert plot of poisson distribution here

A possion GLM is most useful when studying data in which the mean and variance are approximately equal. If they are not not equal, the standard error of the model terms must adjusted to account for the assumption violation.

### Poisson Regression has the following components:

- response count variables,  $Y_i$ , that follows a Possion distribution with mean  $\mu_i$
- ▶ a systematic component,  $\eta_i$ , that relates the explanatory variables,  $\eta_i = \sum_{i=1}^n \beta_i x_{ij}$
- a link function,  $log(\mu_i) = \sum_{j=1}^n \beta_j x_{ij}$

From Poisson regression, we learn the *mean* of each  $Y_i$  given the associated the explanatory variables.

#### Data

We will be consider the bioChemists data set in this section.

This data set contains number of articles produced by PhD biochemistry student during the last 3 years of their PhD.

```
attach(bioChemists)
summary(bioChemists)

```

#### Data

The data set also contains demographic data associated with each student. The data set has five variables:

- art number of articles produced by the student in the last 3 years of their PhD
- ► fem gender
- mar martial status
- kid5 number of children less than 5
- phd pretige of PhD program
- ment number of articles of the mentor in the last 3 years

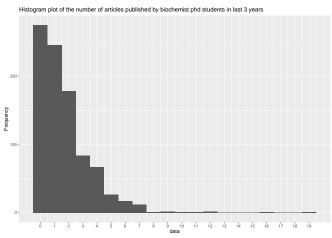

#### Data

```
## art fem mar kid5 phd ment
## "integer" "factor" "numeric" "numeric" "integer"

I convert bioChemists$kid5 from numeric to factor. This will be used later.
```

#### Data Visualization

Plotting the bar graph of bioChemists\$art, we can see that the data looks Poisson-like since there is a large number of observations at 0.

#### Data

We can "quantify" the Poission-ness by analyzing the mean and variance of the data.

```
mean(bioChemists$art)
```

```
## [1] 1.692896
```

```
var(bioChemists$art)
```

```
## [1] 3.709742
```

Although mean and variance are not equal, we will still fit it to Poisson distribution.

### Possion Regression with constant term

To model only the constant term, I use the formula  $\operatorname{art} \sim 1$ . This formula is equivalent to

$$\log \mu_i = \beta_0.$$

# Possion Regression with constant term

```
poisson_model = glm(art ~ 1, family=poisson(link=log),data=bioChemists)
summary(poisson_model)
```

```
##
## Call:
## glm(formula = art ~ 1, family = poisson(link = log), data = bioChemists)
##
## Deviance Residuals:
               10 Median
      Min
                                         Max
## -1.8401 -1.8401 -0.5770 0.2294 7.5677
##
## Coefficients:
              Estimate Std. Error z value Pr(>|z|)
##
## (Intercept) 0.52644 0.02541 20.72 <2e-16 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## (Dispersion parameter for poisson family taken to be 1)
##
      Null deviance: 1817.4 on 914 degrees of freedom
## Residual deviance: 1817.4 on 914 degrees of freedom
## ATC: 3487.1
##
## Number of Fisher Scoring iterations: 5
```

# Possion Regression with constant term

Note that the constant term is the log mean number of counts.

```
print(coef(poisson_model))

## (Intercept)
## 0.5264408

print(log(mean(bioChemists$art)))
```

```
## [1] 0.5264408
```

#### Saturated model

We can again compare the current model to the saturated model (best possible fit).

```
## [1] 3.304511e-62
```

Since our p value is less than 0.05, we reject the null hypothesis. The models are not equivalent.

#### Null model

We can also compare the current model to the null model (worst possible fit).

```
## [1] 1
```

We fail to reject the null hypothesis. This makes sense since the models are literally the same thing.

#### Possion Regression with martial status covariate

To model the martial status covariate, I use the formula art ~ 1+mar. This formula is equivalent to

$$\log \mu_i = \beta_0 + \beta_1 X_{1i}$$

where

$$X_{1i} = \begin{cases} 1 & \text{if mar} = \mathsf{Married} \\ 0 & \text{otherwise} \end{cases}$$
.

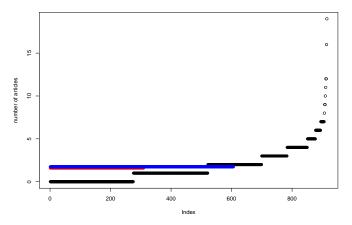

## Possion Regression with martial status covariate

```
poisson_model = glm(art-1+mar , family=poisson(link=log),data=bioChemists)
summary(poisson_model)
```

```
##
## Call:
## glm(formula = art ~ 1 + mar, family = poisson(link = log), data = bioChemists)
##
## Deviance Residuals:
      Min
                10 Median
                                         Max
## -1.8677 -1.7845 -0.5042 0.3107 7.4992
##
## Coefficients:
              Estimate Std. Error z value Pr(>|z|)
##
## (Intercept) 0.46514 0.04508 10.317 <2e-16 ***
## marMarried 0.09117 0.05458 1.671 0.0948 .
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## (Dispersion parameter for poisson family taken to be 1)
##
##
      Null deviance: 1817.4 on 914 degrees of freedom
## Residual deviance: 1814.6 on 913 degrees of freedom
## ATC: 3486.3
##
## Number of Fisher Scoring iterations: 5
```

# Possion Regression with martial status covariate

```
plot(bioChemists$art,ylab='number of articles',xlab = 'Index')
points(poisson_model$fitted[bioChemists$mar=='Single'],col="red")
points(poisson_model$fitted[bioChemists$mar=='Married'],col="blue")
```

Graphically, we can see than that martial status is not good indicator of number articles published.

#### Saturated model

We can again compare the current model to the saturated model (best possible fit).

```
## [1] 4.731233e-62
```

Since our p value is less than 0.05, we reject the null hypothesis. The models are not equivalent and our model is a bad fit.

#### Null model

We can also compare the current model to the null model (worst possible fit).

```
## [1] 1.016236e-70
```

Since our p value is less than 0.05, we reject the null hypothesis. The models are not equivalent. Though our current model does not capture much deviance, the current model captures much more variance than the null model.

#### Anova

```
anova(poisson_model,test="Chisq")
```

```

Contingency table displays number of observations for a given combination of factors.

	low mentor articles	high mentor articles
low articles published	321	200
high articles published	171	223

Contingency table displays number of observations for a given combination of factors.

	low mentor articles	high mentor articles
low articles published	321	200
high articles published	171	223

Log-linear model model the group mean count of each cell of the contingency table

Contingency table displays number of observations for a given combination of factors.

	low mentor articles	high mentor articles
low articles published	321	200
high articles published	171	223

Log-linear model model the group mean count of each cell of the contingency table

Log-linear models allow us to model association between two or more variables.

Contingency table displays number of observations for a given combination of factors.

	low mentor articles	high mentor articles
low articles published	321	200
high articles published	171	223

Log-linear model model the group mean count of each cell of the contingency table

Log-linear models allow us to model association between two or more variables.

There are no well defined explanatory/response variables. This is because we are more focused on the interaction between two variables.

# Contingency Table

Contingency table displays number of observations for all combinations of levels of given discrete variables.

We would like to learn a contigency table for the biochemist data set using number of articles published, number of mentor articles published and number of children.

First, we discretize our continuous variables.

# Contingency Table

# One-Way Contingency Table

A one-way contingency table shows the counts according to one covariate.

```
table(art_relative=bioChemists$art_binary)

## art_relative
## 0 1
## 501 394
```

This one-way contigency table shows that:

- ▶ there are 521 biochemists with 1 or less papers
- ▶ there are 394 biochemists with greater than 1 papers.

# Contingency Table

# Two-Way Contingency Table

A two-way contingency table shows the counts according to two covariates.

```
table(art_relative=bioChemists\art_binary,ment=bioChemists\mathbf{ment_binary})
```

```
## ment
## art_relative 0 1
## 0 321 200
## 1 171 223
```

This two-way contigency table shows that:

- ▶ there are 321 biochemists with 1 or less papers and with a mentor that produced less than or equal to 6 papers
- ▶ there are 200 biochemists with 1 or less papers and with a mentor that produced more than 6 papers

# Contingency Table

# Two-Way Contingency Table

A two-way contingency table shows the counts according to two covariates.

```
table(art_relative=bioChemists$art_binary,ment=bioChemists$ment_binary)
```

```
## ment
## art_relative 0 1
## 0 321 200
## 1 171 223
```

- ▶ there are 171 biochemists with more than 1 paper and with a mentor that produced less than or equal to 6 papers
- ▶ there are 200 biochemists with more than 1 paper and with a mentor that produced more than 6 papers

### Contingency Table

# Three-Way Contingency Table

A three-way contingency table shows the counts according to three covariates.

```
table(art_relative=bioChemists$art_binary,ment=bioChemists$ment_binary,
    kid5=bioChemists$kid5)
```

```
, , kid5 = 0
##
##
               ment
## art_relative
              0 208 128
##
              1 116 147
   , , kid5 = 1
##
               ment
## art_relative
##
              1 38 45
   , , kid5 = 2
##
## art_relative
```

## Contingency Table

# Three-Way Contingency Table

This three-way contigency table shows that:

- With no children,
  - ▶ there are 208 biochemists with 1 or less papers and with a mentor that produced less than or equal to 6 papers
  - ▶ there are 128 biochemists with 1 or less papers and with a mentor that produced more than 6 papers
  - ▶ there are 116 biochemists with more than 1 paper and with a mentor that produced less than or equal to 6 papers
  - ▶ there are 147 biochemists with more than 1 paper and with a mentor that produced more than 6 papers

# Independent Model for two-way contigency table

Remember, using a log-linear model, our primary goal is to learn the interaction effects between covariates.

Again, we build the same two-way contingency table. We need to convert the contigency table in a form that is acceptable to glm.

print(contigency\_table.df)

```
## art_relative ment Freq
## 1 0 0 321
## 2 1 0 171
## 3 0 1 200
## 4 1 1 223
```

Assuming each number of articles and mentor do not affect each other, we build a model of the cell count that does not take into account interaction effects. Such a model is called the *independent* model.

To do this, we use formula Freq ~ art\_relative + ment.

summary(log\_linear\_model\_int)

```
##
## Call:
## glm(formula = Freq ~ art relative + ment, family = poisson, data = contigency table.df)
##
## Deviance Residuals:

	mentor article : 0	mentor article: 1
student article : 0	exp(5.64)	$\exp(5.64 - 0.15)$
mentor article : 1	exp(5.64 - 0.26 - 0.15)	$\exp(5.63 - 0.27 - 0.15)$

#### Goodness of fit

We compare the current model to the saturated model (best possible fit).

```
## [1] 4.243721e-08
```

Since our p value is less than 0.05, we reject the null hypothesis. The models are not equivalent.

### Saturated Model for the two-way contingency table

Assuming each number of articles and mentor affect each other, we build a model of the cell count that takes into account all interaction effects. Such a model is called the *saturated* model. To do this, we use formula Freq ~ art relative\*ment.

### Saturated Model for the two-way contingency table

```
summary(log_linear_model_sat)
```

```
##
## Call:
## glm(formula = Freq ~ art relative * ment, family = poisson, data = contigency table.df)
##
## Deviance Residuals:
## [1] 0 0 0 0

## ATC: 36.973
##
## Number of Fisher Scoring iterations: 2
```

#### Goodness of fit

We compare the current model to the saturated model (best possible fit).

```
## [1] 1
```

We fail to reject the null hypothesis. This makes sense since the models are literally the same thing.

#### Model Comparison

We use anova with test='Chisq' to compare the independent and saturated model.

From anova, we can see that the saturated model provides a statistically significant result.

#### Anova

We use also anova to determine what caused the significant decrease in the deviance.

```
anova(log linear model sat.test='Chisg')
## Analysis of Deviance Table

##
```

#### Goodness of fit

We compare the current model to the saturated model (best possible fit).

We fail to reject the null hypothesis. This makes sense since the models are literally the same thing.

#### Model Comparison

We use anova with test='Chisq' to compare the independent and saturated model.

```
## Analysis of Deviance Table
## Model 1: Freq ~ art_relative + ment + kid5
## Model 2: Freq ~ art_relative + ment + kid5
## Resid. Df Resid. Dev Df Deviance Pr(>Chi)
## 1 10 36.651
## 2 0 0.000 10 36.651 6.501e-05 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

From anova, we can see that the saturated model provides a statistically significant result.

#### Model Comparison

We use also anova to determine what caused the significant decrease in the deviance.

```
anova(log_linear_model_sat,test='Chisq')

```

Adding art\_relative:ment to the independent model caused significant decrease in deviance.

### **Data Wrangling**

Often you'll have to merge the different levels of data and center the predictors.

```
data <- merge(student_data, school_data, by = "id")</pre>
```

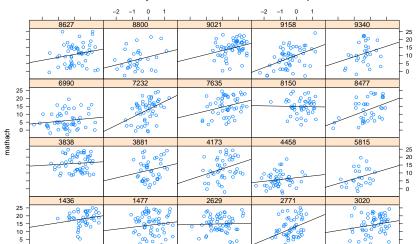

### Data Wrangling

Above we grand-mean centered student SES and school SES, here we're group-mean centering student SES. Which one you use affects the interpretation of the intercept.

```
groups <- unique(data$id)[sample(1:160,20)]
subset <- data[data$id%in%groups, ]</pre>
```

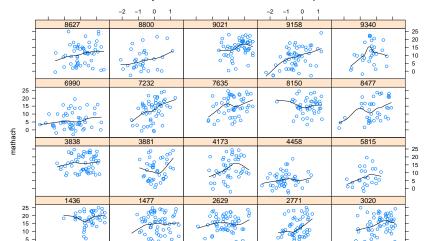

#### Hierarchical models are in order!

#### Variability in Math Achievement ~ SES Relationship

#### Smoothing instead of regression lines.

#### Variability in Math Achievement ~ SES Relationship

It's good practice to start with an unconditional model to have estimates of the variance.
